The company name is ERNI development center Philippines Inc.

Our system is about project management which is based on 6 roles which are admin, sales, Architect, Senior/Expert, Service Unit Leader, and developer, each having their own screen or pages when logged in. Make a necessary database for all of this.

Here's the feature of what they can do and the pages they have:

First make a rolebased login like these:

Admin:
Dashboard(sidebar): This page will display the welcoming message for the user, also will have the basic summary and graphs of the number of technologies/services, users, security reports, and etc.

TechStack(sidebar): this page will allow him to add technologies or services, view the table with status(expiring, active, etc), allow him to renew, price, name, category, and when will it expire. Allow him to edit and delete technology or service. Make it look like an azure pricing estimator.

User Management(sidebar): This page will allow him to view all the users make a table for and allow him to search or sort in the list the table must contain user name(under it is email), department, role, status, and actions like (delete, view full details, and edit) … also in this page allow him to make an account for the user the data he will insert is all the data relevant to the table.

Audit Log(sidebar): this will display all the actions of the users but if something is deleted this will be considered as a backup for the whole system for example the sales accidentally deleted a file or clients this will easily bring back the deleted file if the sales requested it.

settings(sidebar): add usual settings in admin.

Sales:

Dashboard(sidebar): This page will display the welcoming message for the user and reports, also will have the basic summary and graphs of the number of clients, projects, etc. add a schedule container at the right side that will show the schedule allotted for the user

Clients(Sidebar): This page will display table with the content of the name of the clients, progress, status, Deadline and actions buttons(view- allow the user to view, edit and requirements for this client, Delete- allow the user to delete the Clients but when clicked show a confirmations message that explain that it will delete all the file).

Report(Sidebar): In this page the sales/user will see the list of clients and when that specific client clicked it will show the timeline and cost of technologies that architects send, the fee for the usage of the developer(the cost based on the number of days the developer works and the number of people involved), resources(the cost of this is the total number of technology and services this is based on the data sent by the architect) and Others(this is optional but still allow the users to add other fees… just prompt the user to input name and cost allow him to input multiple other fees). The “other fees” must not be shown in the receipt. Then when done add a button to allow the user to save this. This must be sent to the sales receipt.

Receipt(Sidebar): in this page there is a list of clients and when clicked it must show the receipts and allow the user to download the receipt.

Architect:

Dashboard(sidebar): This page will display the welcoming message for the user serves as the central interface for the system architect to monitor and manage all projects assigned for technical evaluation. This page provides an overview of projects that require architectural analysis after the requirements have been gathered by the Sales team. The dashboard typically displays summary information such as the total number of assigned projects, projects currently under review, and projects where the architecture design has already been completed. add a schedule container at the right side that will show the schedule allotted for the user

Projects(sidebar): The Projects Page allows the system architect to view and manage all projects that have been assigned for technical evaluation. This page displays a list of projects that were previously created by the Sales team after gathering the client's requirements. Each project entry has an indication of their status such as pending, in progress and completed.

Project Review(step 1 inside projects after an architect clicks a project): The Project Requirement Review allows the architect to carefully analyze the information collected by the Sales team during client meetings. This page contains essential project details such as meeting notes, Minutes of the Meeting (MOM), requested system features, and the timeline requested by the client.

Technology Stack/Resources Recommendation(step 2 inside projects after the project review): The Technology Stack Recommendation page enables the architect to determine the most suitable technologies that will be used in the development of the system. Based on the reviewed requirements, the architect selects the appropriate tools, frameworks, and platforms that will support the project's functionality, scalability, and performance. It allows the architect to determine the infrastructure and technical resources required to support the system. This includes identifying the appropriate cloud hosting platform, database servers, storage services, and other technical components necessary for system deployment.

Developer Allocation(step 3 inside projects after the tech stack/resources recommendation): It allows the architect to identify the appropriate development team needed to implement the proposed system. Based on the project requirements and technical complexity, the architect

recommends specific roles and expertise required for the development process. The user selects a project complexity level, which dynamically generates a developer pool list featuring critical role shortages (highlighted by alert messages). The main data table lists specific needs by department and skill level, comparing available versus required counts to provide an overall availability status.

Upload Architecture Plan and Workflow Diagram(step 4 inside projects after the developer allocation): The Upload Architecture Plan and Workflow Diagram page allows the system architect to submit the visual and technical documentation of the proposed system architecture. After reviewing the project requirements, recommending the technology stack, identifying the development team, and determining the necessary resources, the architect prepares architectural documents that illustrate how the system will function and how its components will interact.

Summary(step 5 inside projects after the uploads): On this page, the architect can review all prepared documents, ensure that the recommended technologies, team allocation, and system resources are clearly documented, and then submit to SUL to assign for Senior/Expert review the architecture plan and workflow diagram.

Service Unit Leader:

Dashboard(sidebar): This page will display the welcoming message for the user, this will show the summary of all experts or developers , able to see the available to assign and the task or project need to assign with senior or experts which is able to monitor (Overdue, Unassign, In progress, Completed, and To-do). After assigning a task or project they are able to email or notify that expert or senior. Display a pie graph for the overall expert/senior. The Tasks come from or given by . add a schedule container at the right side that will show the schedule allotted for the user

Task Allocation(sidebar): In this page , Service unit leader able to assign to each task the senior/experts. It shows the developer status(Full or Free) and tasks.

Resource Management(sidebar): This page will show the senior/experts , I mean who are them ,their availability and workload.

Performance / Report(sidebar): Monitor how assigned experts are doing, summary of allocations and team performance

Expert/Senior:

	A	B	C
1			
2	Senior BE	1	100%
3	Professional Web	2	100%
4	QA	2	50%
5	UIUX	1	25%

	A	B	C	D	E
1	Feature	Expectation	Min	Most Likely	Max
2	Authentication/Authorization	MS Entra ID, SSO.....	3	5	8

Component	Service	Estimated Cost
Web App	Azure App Service	$13
API	Azure App Service	$13
Database	Azure SQL Database	$5
Storage	Azure Storage	$1
Total		**~$32/month**

Based the information here: https://azure.microsoft.com/en-us/pricing/calculator/

Dashboard(sidebar): This page will display a welcoming message for the user, wherein it shows the project they are currently estimating. The dashboard serves as the main overview for the Senior/Expert, providing a quick summary of all assigned estimation tasks received from the SUL. It displays the list of features pending estimation, features currently in progress, and features already completed and submitted back to the SUL. The dashboard also shows a brief summary of the team composition the Senior/Expert has recommended, including the number of people needed per role and their allocation percentage. Additionally, it presents a snapshot of the infrastructure cost estimation based on Azure pricing, showing the estimated monthly cost per component such as Web App, API, Database, and Storage. The dashboard gives the

Senior/Expert a complete at-a-glance view of everything they need to work on, allowing them to quickly identify which features still need effort estimates and which estimation reports are ready to be submitted back to the SUL for project planning.

Feature Estimation(sidebar): This page allows the Senior/Expert to view and manage the list of features sent by the SUL for estimation. For each feature, the Senior/Expert fills in the expectation and the effort estimate using three values minimum days representing the best case scenario, most likely days representing the realistic timeline, and maximum days representing the worst case scenario. This three-point estimation approach ensures that the project timeline accounts for uncertainty and risk. Each feature also includes an expectation description that clarifies what the feature should do. Once all features are estimated, the Senior/Expert can submit the completed estimation report back to the SUL so that project planning and task allocation can begin.

Team Composition (sidebar): This page allows the Senior/Expert to define the recommended team structure needed to complete the project. Based on the features and their complexity, the Senior/Expert specifies the roles required such as Senior Backend, Professional Web, QA, and UI/UX, along with the number of people needed for each role and their percentage allocation to the project. For example, a Senior Backend developer may be required full time at 100% while a UI/UX designer may only be needed at 25%. This information helps the SUL understand exactly what kind of experts are needed and how many, so they can assign the right developers from the available team.

Cost Estimation(sidebar): This page allows the Senior/Expert to estimate the infrastructure costs required to run the system. Based on the Azure Pricing Calculator at https://azure.microsoft.com/en-us/pricing/calculator/, the Senior/Expert breaks down the cost per component including the Web App, API, Database, and Storage, and maps each component to its corresponding Azure service such as Azure App Service, Azure SQL Database, and Azure Storage. Each component has an estimated monthly cost, and the page automatically calculates the total estimated monthly cost for the entire infrastructure. This gives the Architect, SUL, and client a clear picture of how much the system will cost to host and operate per month.

Developer:

Dashboard(sidebar): This page will display the welcoming message for the user or the developer, wherein able to here the assigned task total of that, overdue, completed, show in pie graph his/her performance and gantt chart schedule container at the right side that will show the schedule allotted for the user

Task(Sidebar): This page shows the assigned task , able to manage it. When click specific assigned it will the kan ban, after done the assign task it will save to the folder

Applies to all roles:

The theme color is skyblue , white and family of blue for professional interface , absorb simple ui for the user , and avoid unnecessary things you will put there.

Navbar: Profile, notifications,dark mode and logout buttons,

Messaging feature(at the corner rightside make it sticky and existing in all pages): allow a real time messaging to improve collaborations allow the user to make group chats or any other kind of messaging format that will help them improve their work.

Folders(Navbar): In this page it will must be shown as a folder per folder are name after each clients and everything inside of it is also folder name of each roles and inside of roles is the name of each people involved in that role and also inside of it is files that the people involved send throughout the project.

Sidebar: it must be collapsable

By the way this is our study and should focus on
Capstone title:A Decision-Driven Project Management Support System for ERNI Development Center Philippines, Incorporation

Description:

ERNI Development Center Philippines, Incorporation is a company engaged in providing software solutions to various clients. One of the challenges encountered by the company is in project management and decision-making, particularly in project planning, task assignment, progress monitoring, and resource utilization. Existing project management practices may lead to delays in decision-making, inefficient use of resources, and difficulty in obtaining a clear and timely overview of project status. This study aims to develop a Decision-Driven Project Management Support System to improve the efficiency, accuracy, and reliability of project-related decisions. The proposed system will support project managers by providing organized project information, progress monitoring, and decision support to enhance overall project coordination and performance. The study will be conducted at ERNI Development Center Philippines, Incorporation, with project managers, developers, and employees involved in project planning and execution as the target respondents. The research will adopt a quantitative research design using descriptive statistics. Data will be collected through structured questionnaires to analyze the current project management process and to assess the need for and effectiveness of the proposed system.
